Self-Normalized Asymptotic Theory in Probability, Statistics and Econometrics. NUS, Singapore

May 22, 2014
Introduction

EPMS Method

Asymptotic Results
- Strong consistency of the EPMS
- Asymp. dist. of the EPMS with continuous payoffs
- Asymp. dist. of the EPMS with discontinuous payoffs

Simulation Study
- GARCH-N model
- GARCH-SG model
- GARCH-DE model
- Coverage rates of the EPMS

Conclusion
1. Introduction

A procedure of financial derivative pricing:

1. Collect data of the underlying assets
2. Model fitting for the prices of the underlying assets under the physical measure ($P$-model)
3. Transform the fitted model to a risk-neutral counterpart ($Q$-model)
4. Compute the no-arbitrage price of a contingent claim under the $Q$-model

Data $\rightarrow P$-model $\rightarrow Q$-model $\rightarrow$ Pricing
1. Introduction (BS)

Data $\rightarrow P$-model $\rightarrow Q$-model $\rightarrow$ Pricing

- BS model under the $P$ measure:

$$dS_t = \mu S_t \, dt + \sigma S_t \, dW_t$$

or

$$d \log S_t = (\mu - 0.5\sigma^2) \, dt + \sigma \, dW_t$$

- Goal: Find a risk-neutral measure $Q$ such that $\{e^{-rt}S_t\}$ is a $Q$-martingale.
1. Introduction (BS)

Theorem (Girsanov’s Theorem)

Let $W_t$ be a Brownian motion on a space $(\Omega, \mathcal{F}, P)$ with information set $\mathcal{F}_t$. Let

$$\Lambda_t = \exp \left\{ \int_0^t \theta(s) dW_s - \frac{1}{2} \int_0^t \theta^2(s) ds \right\}, \ t \leq T,$$

where $\theta(t)$ is a stochastic process satisfying

$$E^P \left\{ \exp \left( \int_0^t \theta^2(s) ds \right) \right\} < \infty.$$ Then,

1. $\Lambda_t$ is a positive $P$-martingale.
2. If $dQ = \Lambda_T dP$, then $E^Q(X) = E^P(\Lambda_T X)$.
3. $W^Q_t = W_t - \int_0^t \theta(s) ds$ is a $Q$-Brownian motion.
In particular, if
\[ \theta(s) = \frac{\mu - r}{\sigma}, \]
then
\[ \Lambda_t = \exp \left\{ \frac{\mu - r}{\sigma} W_t - \frac{1}{2} \left( \frac{\mu - r}{\sigma} \right)^2 t \right\}, \quad t \leq T, \]
and
\[ W_t^Q = W_t + \left( \frac{\mu - r}{\sigma} \right) t \]
is a Brownian motion under Q.

The risk-neutral Q model is
\[ d \log S_t = (r - 0.5\sigma^2) dt + \sigma dW_t^Q \]
1. Introduction (BS)

- Under the $Q$ model, \( \{ e^{-rt} S_t \} \) and \( \{ e^{-rt} f_t \} \) are both $Q$-martingales, where $f_t$ denotes the value of a contingent claim at time $t$. Therefore,

\[
    f_0 = e^{-rT} E^Q(f_T),
\]

where $f_T$ is the payoff of the contingent claim.

- European call option: $f_T = (S_T - K)^+$

- Lookback call option: $f_T = S_T - \min_{0 \leq t \leq T} S_t$

- Up-and-in call option: $f_T = (S_T - K)^+ \delta_{\{ \max_{0 \leq t \leq T} S_t \geq B \}}$
Data $\rightarrow$ \textit{P-model} $\rightarrow$ \textit{Q-model} $\rightarrow$ Pricing

- Particular features of financial data: non-normality, heavy tail, non-constant volatility, volatility clustering, asymmetry distribution, ...

- BS is not suitable to be directly used to depict the dynamics of the prices of the underlying asset.
1. Introduction (GARCH Pricing)

- Two pricing approaches have been adopted in practice: **Estimation** and **Calibration**.

1. Estimation approach: fits the selected model (under $P$) to historical stock prices, transforms the model to the one defined under the risk-neutral measure $Q$, and finally performs the numerical evaluation of the option.

2. Calibration approach: fits the selected model (under $Q$) to currently observed market prices and performs the numerical evaluation of the option.

- We demonstrate the first approach for GARCH models.
1. Introduction (GARCH Pricing)

Data \(\rightarrow\) \textit{P-model} \(\rightarrow\) \textit{Q-model} \(\rightarrow\) Pricing

- Duan (1995)’s \textit{P} model: \(R_t = \log(S_t/S_{t-1})\)

\[
\begin{align*}
R_t &= r + \lambda \sigma_t - 0.5 \sigma_t^2 + \sigma_t \varepsilon_t, \quad \varepsilon_t \sim N(0, 1) \\
\sigma_t^2 &= \alpha_0 + \alpha_1 \sigma_{t-1}^2 \varepsilon_{t-1}^2 + \beta \sigma_{t-1}^2
\end{align*}
\]

- In finance, the parameter \(\lambda\) is often called the market price of risk or the Sharpe ratio.

- BS model:

\[
d \log S_t = (\mu - 0.5\sigma^2) dt + \sigma dW_t
\]
1. Introduction (GARCH Pricing)

Data $\rightarrow$ $P$-model $\rightarrow$ $Q$-model $\rightarrow$ Pricing

- The risk-neutral model is based on the following properties of asset prices:

1. Martingale property under $Q$: $E^Q(e^{r(t+1)}S_{t+1} \mid \mathcal{F}_t) = e^{rt}S_t$.

2. Preserving local higher moments (the type of distribution): As we are considering GARCH models with normal innovations, it suffices to preserve the local variance.

$$\text{var}^Q\left(\log \frac{S_{t+1}}{S_t} \mid \mathcal{F}_{t-1}\right) = \text{var}^P\left(\log \frac{S_{t+1}}{S_t} \mid \mathcal{F}_{t-1}\right).$$
1. Introduction (GARCH Pricing)

Data → $P$-model → $Q$-model → Pricing

- Duan (1995)’s $P$ model:
  \[
  \begin{align*}
  R_t &= r + \lambda \sigma_t - 0.5 \sigma_t^2 + \sigma_t \varepsilon_t, \quad \varepsilon_t \sim N(0, 1) \\
  \sigma_t^2 &= \alpha_0 + \alpha_1 \sigma_{t-1}^2 \varepsilon_{t-1}^2 + \beta \sigma_{t-1}^2
  \end{align*}
  \]

- The risk-neutral $Q$ model obtained by the locally risk-neutral valuation relationship with an expected utility maximizer: let $\xi_t = \lambda + \varepsilon_t$ and then
  \[
  \begin{align*}
  R_t &= r - 0.5 \sigma_t^2 + \sigma_t \xi_t, \quad \xi_t \sim N(0, 1) \\
  \sigma_t^2 &= \alpha_0 + \alpha_1 \sigma_{t-1}^2 (\xi_{t-1} - \lambda)^2 + \beta \sigma_{t-1}^2
  \end{align*}
  \]

- BS $Q$-model: $d \log S_t = (r - 0.5 \sigma^2) dt + \sigma dW_t^Q$
1. Introduction (con.)

Data $\rightarrow$ $P$-model $\rightarrow$ $Q$-model $\rightarrow$ Pricing

- We don’t have an explicit representation for the distribution of $R_T$ (or $S_T$). Thus, the no-arbitrage price is approximated by

$$f_0 = e^{-rT} E^Q(f_T) \approx e^{-rT} \frac{1}{n} \sum_{i=1}^{n} f_T(S_{t,i}, 0 \leq t \leq T),$$

where the random paths of the stock prices $S_{t,i}$ are generated independently from the $Q$ model for $i = 1, \ldots, n$.

- This is called the standard Monte Carlo simulation method.
Data $\rightarrow$ \textit{P}-model $\rightarrow$ \textit{Q}-model $\rightarrow$ \textbf{Pricing}

- Monte Carlo simulation (MCS) is a natural tool and has been commonly used for solving this problem (Boyle, 1977; Kemna and Vorst, 1990; Duan, 1995; Boyle et al., 1997).

- The computational effort of the standard MCS usually increases dramatically if high precision in option pricing is required.
Duan and Simonato (1998) proposed an empirical martingale simulation (EMS) to improve the efficiency of the MCS under a risk-neutral framework.

The advantage of the EMS is that it can be easily incorporated into the widely known variance reduction procedures, such as antithetic and control-variate simulations, and it is truly simple and practically requires no additional programming efforts.
1. Introduction (con.)

Data $\rightarrow P$-model $\rightarrow Q$-model $\rightarrow$ Pricing
Data $\rightarrow P$-model $\rightarrow \rightarrow \rightarrow \rightarrow \rightarrow$ Pricing

- However, to obtain the explicit expression of a risk-neutral model is not convenient when dealing with a complex model.

- This study proposes a modification of the EMS from the framework under a risk-neutral measure to a dynamic $P$ measure. Thus, we call it EPMS.
Let $\Lambda_T$ denote a Radon-Nikodým derivative of a $Q$ measure with respect to the dynamic $P$ measure.

For any given payoff $f_T$ of a contingent claim, note that

$$E^Q(f_T) = E^P(f_T\Lambda_T),$$

where $dQ = \Lambda_T dP$.

Generate random paths under $P$ measure (i.e., from the physical model)
2 EPMS (con.)

1. Generate $n$ random paths of the stock prices, $S_{t,i}$, $i = 1, 2, \ldots, n$, $t = 0, 1, \ldots, T$, from the dynamic GARCH model.

- Standard Monte Carlo simulation:

  \begin{align*}
  \text{path 1} & \quad S_{0,1} & S_{1,1} & S_{2,1} & \cdots & S_{T,1} \\
  \text{path 2} & \quad S_{0,2} & S_{1,2} & S_{2,2} & \cdots & S_{T,2} \\
  \vdots & \quad \vdots & \quad \vdots & \quad \vdots & \quad \vdots \\
  \text{path n} & \quad S_{0,n} & S_{1,n} & S_{2,n} & \cdots & S_{T,n}
  \end{align*}
2. The first adjusting step: Assume $\Lambda_t$ being a change of measure process and denote $\Lambda_{t,i} = \Lambda_t(S_{u,i}, 0 \leq u \leq t)$. Let $\tilde{\Lambda}_{0,i} = \Lambda_{0,i} = 1$ and define $\tilde{\Lambda}_{t,i}$, $i = 1, \ldots, n$, iteratively by

$$
\tilde{\Lambda}_{t,i} = \frac{W_i(t, n)}{W_0(t, n)},
$$

where $W_i(t, n) = \frac{\tilde{\Lambda}_{t-1,i}}{\Lambda_{t-1,i}} \Lambda_{t,i}$ and $W_0(t, n) = \frac{1}{n} \sum_{i=1}^{n} W_i(t, n)$. 

Huang, S. F.
3. The second adjusting step: Let \( \tilde{S}_{0,i} = S_0 \) and define the empirical martingale stock prices \( \tilde{S}_{t,i}, i = 1, \ldots, n \), iteratively by

\[
\tilde{S}_{t,i} = S_0 \frac{Z_i(t, n)}{Z_0(t, n)},
\]

where \( Z_i(t, n) = \frac{\tilde{S}_{t-1,i}}{\tilde{S}_{t-1,i}} \tilde{S}_{t,i} \) and

\[
Z_0(t, n) = \frac{e^{-rt}}{n} \sum_{i=1}^{n} Z_i(t, n) \tilde{\Lambda}_{t,i}.
\]

4. Approximate $f_0$ by

$$\tilde{f}_0 = e^{-rT} \frac{1}{n} \sum_{i=1}^{n} \tilde{f}_{T,i} \tilde{\Lambda}_{T,i}, \quad (\text{vs. } f_0 = E^P(e^{-rT} f_T \Lambda_T))$$

where $\tilde{f}_{T,i} = f_T(\tilde{S}_{t,i}; \ t = 0, 1, \ldots, T)$. 
Both $\tilde{\Lambda}_{t,i}$ and $\tilde{S}_{t,i}$ satisfy the “empirical $P$-martingale property”:

$$\tilde{\Lambda}_{0,i} = \frac{1}{n} \sum_{i=1}^{n} \tilde{\Lambda}_{t,i} \quad (\text{vs.} \quad \Lambda_0 = E^P(\Lambda_t)),$$

and

$$S_0 = \frac{1}{n} \sum_{i=1}^{n} e^{-rt} \tilde{S}_{t,i} \tilde{\Lambda}_{t,i} \quad (\text{vs.} \quad S_0 = E^P(e^{-rt} S_t \Lambda_t)),$$

for any integer $n$ and $t = 1, \ldots, T$. 
3 Asymptotic Results

3.1 Strong consistency of the EPMS

**Theorem 1**

Let \( \{e^{-rt} S_t \Lambda_t\} \) be a positive \( P \)-martingale process over the time index set \( \{t : t = 0, 1, \ldots, T\} \). Suppose that the payoff function, \( f(S_1, \ldots, S_T) \), satisfies \( E^Q(|f(S_1, \ldots, S_T)|) < \infty \) and is Lipschitz continuous. Then we have

\[
n^{-1} \sum_{i=1}^{n} \left\{ f(\tilde{S}_{1,i}, \ldots, \tilde{S}_{T,i}) \tilde{\Lambda}_{T,i} \right\} \rightarrow E_0\{f(S_1, \ldots, S_T) \Lambda_T\},
\]

almost surely, as \( n \rightarrow \infty \), where \( \tilde{\Lambda}_{t,i} \) and \( \tilde{S}_{t,i} \) are generated by the EPMS.
3.1 Strong consistency of the EPMS (con.)

- For example, the payoff functions of European calls, \((S_T - K)^+\), are Lipschitz continuous.

- However, some payoff functions of contingent claims do not satisfy the Lipschitz continuity, like the digital,
  \(f(S_T) = \delta_{\{S_T > K\}}\), and barrier
  \(f(S_t, 0 \leq t \leq T) = (S_T - K)^+\delta_{\{S_{\max} \geq B\}}\), options.
3.1 Strong consistency of the EPMS (con.)

In order to accommodate the case of discontinuous payoff functions, the Lipschitz continuity is replaced by the following generic Lipschitz condition.

**Definition 1**

A function $f(x)$, mapping from $R^m_+$ to $R$, is said to satisfy the generic Lipschitz condition if there exists $q < \infty$ such that

$$|f(x)| < q(1 + ||x||)$$

for any $x \in R^m_+$, where $|| \cdot ||$ stands for the Euclidean norm, and there exists a finite partition, $A_\ell$, $\ell = 1, \ldots, k$, of its domain such that each $A_\ell$ is a connected set and $f(\cdot)$ is Lipschitz continuous over any $A_\ell$. 
3.1 Strong consistency of the EPMS (con.)

**Theorem 2**

Let \( \{e^{-rt} S_t \Lambda_t\} \) be a positive \( P \)-martingale process over the time index set \( \{t : t = 0, 1, \ldots, T\} \). If the payoff function, \( f(S_1, \ldots, S_T) \), satisfies \( E^Q(|f(S_1, \ldots, S_T)|) < \infty \) and the **generic Lipschitz condition**, and the multivariate distribution of \( (S_1, \ldots, S_T) \) under \( Q \) has a bounded density function, then as \( n \to \infty \),

\[
n^{-1} \sum_{i=1}^{n} \{f(\tilde{S}_{1,i}, \ldots, \tilde{S}_{T,i}) \tilde{\Lambda}_{T,i}\} \to E_0\{f(S_1, \ldots, S_T) \Lambda_T\},
\]

almost surely, where \( \tilde{\Lambda}_{t,i} \) and \( \tilde{S}_{t,i} \) are generated by the EPMS.
3.2 Asymp. dist. of the EPMS with piecewise smooth and continuous payoffs

- Let $f : \mathbb{R} \to \mathbb{R}$ be a piecewise smooth and continuous function:

$$f(x) = \sum_{j=1}^{m+1} f_j(x) \delta_{A_j}(x),$$

where $A_j$’s form a partition of $\mathbb{R}$.

- $A_1 = (-\infty, k_1)$, $A_j = [k_{j-1}, k_j)$, for $j = 2, 3, \ldots, m+1$ and $k_{m+1} = \infty$, and $\delta_{A}(\cdot)$ is an indicator function.

- $f_j$’s have continuous first order derivatives and $f_j(k_j) = f_{j+1}(k_j)$, $j = 1, \ldots, m$, to ensure the continuity of $f$. 
3.2 Asymp. dist. of the EPMS with continuous payoffs (con.)

- We use $f'(x)$ to denote the right first derivative and write

$$f'(x) = \sum_{j=1}^{m+1} f'_j(x) \delta_{A_j}(x).$$

\[2\]

**Definition 2**

A function $f : \mathbb{R} \to \mathbb{R}$ is said to have a polynomial growth rate $q$ if there exist a constant $C > 0$ and a positive integer $q$ such that for any real number $x \in \mathbb{R}$, $|f(x)| \leq C(1 + |x|^q)$. 

Huang, S. F.
Theorem 3

Let the asset price $S_T$ be a positive random variable with a continuous distribution, $\Lambda_T$ be a Radon-Nikodým derivative, and the payoff function $f(S_T)$ be piecewise smooth and continuous as defined in (1). If $f'(\cdot)$ exists and has a polynomial growth rate $q$, $E(S_T^{2(q+1)}\Lambda_T^2) < \infty$ and $E(\Lambda_T^2) < \infty$, then

$$\sqrt{n}(C_{EPMS}^{(n)} - C) \xrightarrow{\mathcal{L}} \mathcal{N}(0, V), \quad \text{as } n \to \infty,$$

where $C$ is the true derivative price, $\xrightarrow{\mathcal{L}}$ denotes convergence in distribution, and
3.2 Asymp. dist. of the EPMS with continuous payoffs (con.)

Theorem 3 (con.)

\[ V = e^{-2rT} \left( \text{Var}[f(S_T)\Lambda_T] + \text{Var}[S_T\Lambda_T]\Phi^2 + \text{Var}[\Lambda_T]\Psi^2 - 2\{\Phi\text{Cov}[f(S_T)\Lambda_T, S_T\Lambda_T] + \Psi\text{Cov}[f(S_T)\Lambda_T, \Lambda_T] - \Phi\Psi\text{Cov}[S_T\Lambda_T, \Lambda_T]\} \right), \]

in which \( \Phi = e^{-rT}E[f'(S_T)S_T\Lambda_T]/S_0 \), and \( \Psi = E[f(S_T)\Lambda_T] - S_0e^{rT}\Phi \).
3.3 Asymp. dist. of the EPMS with piecewise smooth and discontinuous payoffs

- In financial markets, there are derivative contracts with discontinuous payoffs such as the binary (digital) options.

- Yuan and Chen (2009): a conjecture for the asymptotic distribution of the EMS estimator when the payoffs are discontinuous.

- We derive the asymptotic distribution of the EPMS estimator when $f$ is discontinuous.
3.3 Asymp. dist. of the EPMS with discontinuous payoffs
(con.)

Theorem 4

Let the asset price $S_T$ be a positive continuous random variable with density function $p(\cdot, T)$, $\Lambda_T$ be a Radon-Nikodým derivative, and $f(S_T)$ be a piecewise smooth and discontinuous payoff function that jumps at $k_i$ with jump height $J_i$, $i = 1, \ldots, m$. If $f'(\cdot)$ exists and has a polynomial growth rate $q$, $E(S_T^{2(q+1)}\Lambda_T^2) < \infty$ and $E(\Lambda_T^2) < \infty$, then

$$\sqrt{n}(C_{EPMS}^{(n)} - C) \xrightarrow{\mathcal{L}} \mathcal{N}(0, V^*), \quad \text{as } n \to \infty,$$

where $C$ is the true derivative price and
3.3 Asymp. dist. of the EPMS with discontinuous payoffs
(con.)

**Theorem 4 (con.)**

\[
V^* = e^{-2rT} \left( \text{Var}[f(S_T)\Lambda_T] + \text{Var}[S_T\Lambda_T]\Phi^*^2 + \text{Var}[\Lambda_T]\Psi^*^2 \\
- 2\{\Phi^*\text{Cov}[f(S_T)\Lambda_T, S_T\Lambda_T] + \Psi^*\text{Cov}[f(S_T)\Lambda_T, \Lambda_T] \\
- \Phi^*\Psi^*\text{Cov}[S_T\Lambda_T, \Lambda_T]\} \right),
\]

(4)

in which \(\Phi^* = \Phi + \frac{1}{S_0e^{rT}} \sum_{i=1}^{m} J_i k_i \Lambda_T(k_i) \times p(k_i, T)\) and
\(\Psi^* = E[f(S_T)\Lambda_T] - S_0e^{rT}\Phi^*\).
3.3 Asymp. dist. of the EPMS with discontinuous payoffs (con.)

- If there is no jump, then $J_i$’s are zero and the $V^*$ in Theorem 4 reduces to $V$ in Theorem 3.

- If the measures $P$ and $Q$ coincide, i.e., $\Lambda_T = 1$, then the EPMS reduces to the EMS.
4 Simulation Study

- GARCH models with normal, shifted gamma and double exponential innovations are considered.

- The change of measure process: the Esscher transform

- The coverage rates of the EPMS price estimator are investigated when the payoff are continuous or discontinuous.
Esscher transform

- Let the density of the log returns under the $P$ measure be $g(x)$ and the density of the log returns under the $Q$ measure be

$$g(x; \theta) \propto e^{\theta x} g(x)$$

- The parameter $\theta$ is chosen such that $e^{-rt} S_t$ is a $Q$ martingale.
4.1 GARCH-N model

- Duan (1995):

\[
\begin{cases}
R_t = r + \lambda \sigma_t - 0.5 \sigma_t^2 + \sigma_t \varepsilon_t, & \varepsilon_t \sim N(0, 1) \\
\sigma_t^2 = \alpha_0 + \alpha_1 \sigma_{t-1}^2 + \beta \sigma_{t-1}^2
\end{cases}
\]  

(5)

**Proposition 1**

For Model (5), the change of measure process \( \Lambda^\text{ess}_t \) derived by the Esscher transform is

\[
\Lambda^\text{ess}_t = \prod_{k=1}^{t} \exp\{ -[\lambda^2 \sigma_k^2 + 2\lambda \sigma_k (R_k - \mu_k)]/(2\sigma_k^2) \},
\]

where \( \mu_k = r + \lambda \sigma_k - 0.5 \sigma_k^2 \).
The risk-neutral GARCH-N counterpart of Model (5) under the $Q^{ess}$ measure is written as follows,

$$\begin{align*}
R_t &= r - 0.5 \sigma_t^2 + \sigma_t \xi_t, \quad \xi_t \sim N(0, 1) \\
\sigma_t^2 &= \alpha_0 + \alpha_1 \sigma_{t-1}^2 (\xi_{t-1} - \lambda)^2 + \beta \sigma_{t-1}^2
\end{align*}$$

which is the same as Duan (1995)'s result derived from the locally risk-neutral valuation relationship with an expected utility maximizer.
4.1 GARCH-N model (con.)

- Parameter setting (Duan and Simonato, 1998):
  \( S_0 = 100, \ r = 0.10 \) (annualized and 1 year = 365 days),
  \( \alpha_0 = 0.00001, \ \alpha_1 = 0.20, \ \beta_1 = 0.70, \ \lambda = 0.01, \ T = 1, 3, 9 \)
  months, \( S_0/K = 0.9, 1, 1.1 \), and \( \sigma_1^2 = \alpha_0/(1 - \alpha_1 - \beta_1) \).

- Denote the ratios of the standard deviations obtained by the MCS, EMS and EPMS with 10,000 sample paths and 100 replications as

\[
RS_1 \equiv \frac{\text{std.}(\text{MCS})}{\text{std.}(\text{EPMS})}
\]

and

\[
RS_2 \equiv \frac{\text{std.}(\text{EMS})}{\text{std.}(\text{EPMS})}.
\]

</table>
4.1 GARCH-N model (con.)

- The EPMS is comparable to the EMS and the relative efficiency of the EPMS against the MCS increases as the time to maturity increases in most cases.
4.2 GARCH-SG model

- Siu, Tong and Yang (2004):

\[
\begin{align*}
R_t &= r + \lambda \sigma_t - 0.5 \sigma_t^2 + \sigma_t \varepsilon_t, \quad \varepsilon_t \sim SG(0, 1, a) \\
\sigma_t^2 &= \alpha_0 + \alpha_1 \sigma_{t-1}^2 \varepsilon_{t-1}^2 + \beta \sigma_{t-1}^2 
\end{align*}
\]  

(7)

**Proposition 2**

For Model (7), the change of measure process \( \Lambda_t^{ess} \) derived by the Esscher transform is

\[
\Lambda_t^{ess} = \prod_{k=1}^{t} \left( 1 - \delta_k^* \sigma_k / \sqrt{a} \right)^a \exp\{\delta_k^* (R_k - \mu_k + \sqrt{a} \sigma_k)\},
\]

where \( \mu_k = r + \lambda \sigma_k - 0.5 \sigma_k^2 \), \( \delta_k^* = \sqrt{a} / \sigma_k - b^q_k \) and

\[
b^q_k = \left[ 1 - \exp\{(\mu_k - r - \sqrt{a} \sigma_k) / a\} \right]^{-1}.
\]
The risk-neutral GARCH-SG counterpart of Model (7) under the $Q^{ess}$ measure is written as follows,

\[
\begin{align*}
R_t &= r + \lambda \sigma_t - 0.5 \sigma_t^2 - \sqrt{a}(\sigma_t - \sigma_t^*) + \sigma_t^* \xi_t^*, \quad \xi_t^* \sim SG(0, 1, a) \\
\sigma_t^2 &= \alpha_0 + \alpha_1 \{\sigma_{t-1}^* \xi_{t-1}^* + \sqrt{a}(\sigma_{t-1}^* - \sigma_{t-1})\}^2 + \beta \sigma_{t-1}^2
\end{align*}
\]

(8)

where $\sigma_t^* = \sqrt{a}/b_t^q$ and $b_t^q$ are defined as in Proposition 2.

4.2 GARCH-DE model

Consider the following GARCH model:

\[
\begin{align*}
R_t &= r + \lambda \sigma_t - 0.5 \sigma_t^2 + \sigma_t \varepsilon_t, \quad \varepsilon_t \sim DE(0, 1) \\
\sigma_t^2 &= \alpha_0 + \alpha_1 \sigma_{t-1}^2 \varepsilon_{t-1}^2 + \beta \sigma_{t-1}^2
\end{align*}
\]  \quad (9)

Proposition 2

For Model (9), the change of measure process \( \Lambda_t^{\text{ess}} \) derived by the Esscher transform is

\[
\Lambda_t^{\text{ess}} = \prod_{k=1}^{t} [1 - 0.5 (\delta_k^* \sigma_k)^2] \exp\{\delta_k^* (R_k - \mu_k)\},
\]

where \( \mu_k = r + \lambda \sigma_k - 0.5 \sigma_k^2 \),

\[
\delta_k^* = \{-\sigma_k + [a_k \sigma_k^2 + 2(a_k - 1)^2]^{0.5}\} / [\sigma_k (1 - a_k)] \quad \text{and}
\]

\[
a_k = \exp(\lambda \sigma_k - 0.5 \sigma_k^2).
\]

</table>
5 Conclusion

- An EPMS is proposed to improve the efficiency of computing the no-arbitrage prices under the dynamic $P$ measure.

- The proposed method can be applied to compute the no-arbitrage prices even when the risk-neutral model cannot be expressed explicitly.

- The strong consistency and the asymptotic normality of the EPMS estimator are established.
5 Conclusion (con.)

- Simulation results show that the EPMS is comparable to the EMS and the relative efficiency of the EPMS against the MCS increases as the time to maturity increases.

- Simulation results also show that the asymptotically normal distribution serves as a persuasive approximation for samples consisting of as few as 500 simulation paths.

- The extensions to path-dependent contingent claims or high-dimensional payoffs are interesting topics, and we refer these extensions to our future study.
Thank You for Your Attention!
